

Video on how I did this here: <https://youtu.be/WNXcGU7ZWpk>

Steps on how I solved this:

1. Goto WP Optimze, toggle minify to see if that's causing the problem
2. Test the form for outputs, take note of them
3. Check the database
4. Download Node
5. Create a new folder;
6. Open terminal and cd to the folder
7. Input: npx create-react-app nameofapp
8. Open the folder in a code editor
9. Write your code
10. Input npm start to check your page
11. Input npm run build to create a build folder
12. Drag build folder into apps under reactpress/apps/calworks-calculator in file manager

Steps for bringing in React App into Wordpress:

1. Go to <https://github.com/SF-LivingWageCoalition/CalWORKs-Calculator>
2. Open your terminal
3. Goto where you want to put the code
4. Type in:  
git clone https://github.com/emhuang3/CalWORKs-Calculator.git
5. Change what you need to
6. Type this into the terminal:  
npm run build  
This will create a build folder of the app
7. Login to Wordpress
8. Head to file manager
9. Goto wp-content -> reactpress -> apps -> calworks-calculator
10. Delete build folder
11. Drag and drop in new build folder
12. If it looks weird goto WP Optimize in the menu sidebar and goto minify
13. Toggle minify to see if that's causing the problem, if so you need to figure out which files are being combined
